Task 3

1.Which SQL command is used to insert new records into a table?

The INSERT INTO command is used to add new rows of data to a table.

2.What is the difference between DELETE and TRUNCATE in SQL?

DELETE is a DML command that removes rows one by one and can be filtered using a WHERE clause. TRUNCATE is a DDL command that removes all rows at once, cannot use a WHERE clause, and is much faster.

3.Which DML command is used to modify existing values in a table?

The UPDATE command is used to modify existing records in a table.

4.Can a single INSERT statement add multiple rows at once?

Yes, a single INSERT statement can add multiple rows at once by providing a comma-separated list of value sets.

5.Which DML command is used to fetch records from one or more tables?

The SELECT command is used to retrieve data from a database.

6.What is the purpose of using a JOIN in SQL?

The purpose of a JOIN is to combine rows from two or more tables based on a related column between them.

7.Which JOIN returns only the rows that have matching values in both tables?

An INNER JOIN returns only the rows where the joined keys exist in both tables.

8.What does a LEFT JOIN return when there is no matching row in the right table?

When there is no matching row in the right table, a LEFT JOIN returns the row from the left table and fills the columns from the right table with NULL values.

9.Can MySQL directly perform a FULL OUTER JOIN? If not, how can it be achieved?

No, MySQL does not have a dedicated FULL OUTER JOIN keyword. It can be simulated by combining a LEFT JOIN and a RIGHT JOIN with a UNION operator.

10.What is the difference between INNER JOIN and CROSS JOIN?

An INNER JOIN requires an ON clause to specify a matching condition and returns only the rows that satisfy this condition. A CROSS JOIN does not require a condition and returns the Cartesian product of the two tables, combining every row from the first table with every row from the second table.
